1 Mathematical Special Functions

1.1 Introduction and History

The first significant library upgrade on the road to C++2011, [TR1](#), included a set of 23 mathematical functions that significantly extended the standard transcendental functions inherited from C and declared in `<cmath>`.

Although most components from TR1 were eventually adopted for C++11 these math functions were left behind out of concern for implementability. The math functions were published as a separate international standard [IS 29124 - Extensions to the C++ Library to Support Mathematical Special Functions](#).

For C++17 these functions were incorporated into the main standard.

1.2 Contents

The following functions are implemented in namespace `std`:

- [assoc_laguerre](#) - Associated Laguerre functions
- [assoc_legendre](#) - Associated Legendre functions
- [beta](#) - Beta functions
- [comp_ellint_1](#) - Complete elliptic functions of the first kind
- [comp_ellint_2](#) - Complete elliptic functions of the second kind
- [comp_ellint_3](#) - Complete elliptic functions of the third kind
- [cyl_bessel_i](#) - Regular modified cylindrical Bessel functions
- [cyl_bessel_j](#) - Cylindrical Bessel functions of the first kind
- [cyl_bessel_k](#) - Irregular modified cylindrical Bessel functions
- [cyl_neumann](#) - Cylindrical Neumann functions or Cylindrical Bessel functions of the second kind
- [ellint_1](#) - Incomplete elliptic functions of the first kind
- [ellint_2](#) - Incomplete elliptic functions of the second kind
- [ellint_3](#) - Incomplete elliptic functions of the third kind
- [expint](#) - The exponential integral
- [hermite](#) - Hermite polynomials
- [laguerre](#) - Laguerre functions
- [legendre](#) - Legendre polynomials
- [riemann_zeta](#) - The Riemann zeta function

- [sph_bessel](#) - Spherical Bessel functions
- [sph_legendre](#) - Spherical Legendre functions
- [sph_neumann](#) - Spherical Neumann functions

The hypergeometric functions were stricken from the TR29124 and C++17 versions of this math library because of implementation concerns. However, since they were in the TR1 version and since they are popular we kept them as an extension in namespace `__gnu_cxx`:

- `conf_hyperg` - Confluent hypergeometric functions
- `hyperg` - Hypergeometric functions

1.3 General Features

1.3.1 Argument Promotion

The arguments supplied to the non-suffixed functions will be promoted according to the following rules: 1. If any argument intended to be floating point is given an integral value That integral value is promoted to double. 2. All floating point arguments are promoted up to the largest floating point precision among them.

1.3.2 NaN Arguments

If any of the floating point arguments supplied to these functions is invalid or NaN (`std::numeric_limits<Tp>::quiet_NaN`), the value NaN is returned.

1.4 Implementation

We strive to implement the underlying math with type generic algorithms to the greatest extent possible. In practice, the functions are thin wrappers that dispatch to function templates. Type dependence is controlled with `std::numeric_limits` and functions thereof.

We don't promote `float` to `double` or `double` to `long double` reflexively. The goal is for `float` functions to operate more quickly, at the cost of `float` accuracy and possibly a smaller domain of validity. Similarly, `long double` should give you more dynamic range and slightly more precision than `double` on many systems.

1.5 Testing

These functions have been tested against equivalent implementations from the [Gnu Scientific Library](http://www.gnu.org/software/scientific/), [GSL](http://www.boost.org/doc/libs/1_60_0/libs/math/doc/html/index.html) and [Boost](http://www.boost.org/doc/libs/1_60_0/libs/math/doc/html/index.html) and the ratio

$$\frac{|f - f_{test}|}{|f_{test}|}$$

is generally found to be within 10^{-15} for 64-bit double on linux-x86_64 systems over most of the ranges of validity.

Todo Provide accuracy comparisons on a per-function basis for a small number of targets.

3.1 Adaptors for pointers to functions

Collaboration diagram for Adaptors for pointers to functions:

Classes

- class `std::pointer_to_binary_function< _Arg1, _Arg2, _Result >`
- class `std::pointer_to_unary_function< _Arg, _Result >`

Functions

- template<typename _Arg, typename _Result >
`pointer_to_unary_function< _Arg, _Result > std::ptr_fun (_Result(*)(_Arg))`
- template<typename _Arg1, typename _Arg2, typename _Result >
`pointer_to_binary_function< _Arg1, _Arg2, _Result > std::ptr_fun (_Result(*)(_Arg1, _Arg2))`

3.1.1 Detailed Description

The advantage of function objects over pointers to functions is that the objects in the standard library declare nested typedefs describing their argument and result types with uniform names (e.g., `result_type` from the base classes `unary_function` and `binary_function`). Sometimes those typedefs are required, not just optional.

Adaptors are provided to turn pointers to unary (single-argument) and binary (double-argument) functions into function objects. The long-winded functor `pointer_to_unary_function` is constructed with a function pointer `f`, and its `operator()` called with argument `x` returns `f(x)`. The functor `pointer_to_binary_function` does the same thing, but with a double-argument `f` and `operator()`.

The function `ptr_fun` takes a pointer-to-function `f` and constructs an instance of the appropriate functor.

3.1.2 Function Documentation

3.1.2.1 `template<typename _Arg, typename _Result > pointer_to_unary_function<_Arg, _Result> std::ptr_fun (_Result(*)(_Arg) __x) [inline]`

One of the [adaptors for function pointers](#).

3.1.2.2 `template<typename _Arg1, typename _Arg2, typename _Result > pointer_to_binary_function<_Arg1, _Arg2, _Result> std::ptr_fun (_Result(*)(_Arg1, _Arg2) __x) [inline]`

One of the [adaptors for function pointers](#).

3.2 Adaptors for pointers to members

- class `std::mem_fun_t<_Ret, _Tp>`

Functions

- `template<typename _Ret, typename _Tp>`
`mem_fun_t<_Ret, _Tp> std::mem_fun (_Ret(_Tp::*__f)())`
- `template<typename _Ret, typename _Tp, typename _Arg>`
`mem_fun1_t<_Ret, _Tp, _Arg> std::mem_fun (_Ret(_Tp::*__f)(_Arg))`
- `template<typename _Ret, typename _Tp>`
`mem_fun_ref_t<_Ret, _Tp> std::mem_fun_ref (_Ret(_Tp::*__f)())`
- `template<typename _Ret, typename _Tp, typename _Arg>`
`mem_fun1_ref_t<_Ret, _Tp, _Arg> std::mem_fun_ref (_Ret(_Tp::*__f)(_Arg))`

3.2.1 Detailed Description

There are a total of $8 = 2^3$ function objects in this family. (1) Member functions taking no arguments vs member functions taking one argument. (2) Call through pointer vs call through reference. (3) Const vs non-const member function.

All of this complexity is in the function objects themselves. You can ignore it by using the helper function `mem_fun` and `mem_fun_ref`, which create whichever type of adaptor is appropriate.

3.15.1 Detailed Description

These algorithms are variations of a classic binary search, and all assume that the sequence being searched is already sorted.

The number of comparisons will be logarithmic (and as few as possible). The number of steps through the sequence will be logarithmic for random-access iterators (e.g., pointers), and linear otherwise.

The LWG has passed Defect Report 270, which notes: *The proposed resolution reinterprets binary search. Instead of thinking about searching for a value in a sorted range, we view that as an important special case of a more general algorithm: searching for the partition point in a partitioned range. We also add a guarantee that the old wording did not: we ensure that the upper bound is no earlier than the lower bound, that the pair returned by equal_range is a valid range, and that the first part of that pair is the lower bound.*

The actual effect of the first sentence is that a comparison functor passed by the user doesn't necessarily need to induce a strict weak ordering relation. Rather, it partitions the range.

3.15.2 Function Documentation

3.15.2.1 `template<typename _ForwardIterator, typename _Tp> bool std::binary_search (_ForwardIterator __first, _ForwardIterator __last, const _Tp & __val)`

Determines whether an element exists in a range.

Parameters

<code>__first</code>	An iterator.
<code>__last</code>	Another iterator.
<code>__val</code>	The search term.

Returns

True if `__val` (or its equivalent) is in `[__first, __last]`.

Note that this does not actually return an iterator to `__val`. For that, use `std::find` or a container's specialized find member functions.

Definition at line 2244 of file `stl_algo.h`.

3.15.2.2 `template<typename _ForwardIterator, typename _Tp, typename _Compare> bool std::binary_search (_ForwardIterator __first, _ForwardIterator __last, const _Tp & __val, _Compare __comp)`

Determines whether an element exists in a range.

Parameters

<code>__first</code>	An iterator.
<code>__last</code>	Another iterator.
<code>__val</code>	The search term.
<code>__comp</code>	A functor to use for comparisons.

Returns

True if `__val` (or its equivalent) is in `[__first, __last]`.

Note that this does not actually return an iterator to `__val`. For that, use `std::find` or a container's specialized find member functions.

The comparison function should have the same effects on ordering as the function used for the initial sort.

3.15.2.3 `template<typename _ForwardIterator, typename _Tp> pair<_ForwardIterator, _ForwardIterator> std::equal_range (_ForwardIterator __first, _ForwardIterator __last, const _Tp & __val) [inline]`

Finds the largest subrange in which `__val` could be inserted at any place in it without changing the ordering.

Parameters

<code>__first</code>	An iterator.
<code>__last</code>	Another iterator.
<code>__val</code>	The search term.

Returns

An pair of iterators defining the subrange.

This is equivalent to

```
std::make_pair(lower_bound(__first, __last, __val),
               upper_bound(__first, __last, __val))
```

but does not actually call those functions.

3.16.1 Detailed Description

Binders turn functions/functors with two arguments into functors with a single argument, storing an argument to be applied later. For example, a variable `B` of type `binder1st` is constructed from a functor `f` and an argument `x`. Later, `B`'s `operator()` is called with a single argument `y`. The return value is the value of `f(x, y)`. `B` can be *called* with various arguments (`y1, y2, ...`) and will in turn call `f(x, y1), f(x, y2), ...`

The function `bind1st` is provided to save some typing. It takes the function and an argument as parameters, and returns an instance of `binder1st`.

The type `binder2nd` and its creator function `bind2nd` do the same thing, but the stored argument is passed as the second parameter instead of the first, e.g., `bind2nd(std::minus<float>(), 1.3)` will create a functor whose `operator()` accepts a floating-point number, subtracts 1.3 from it, and returns the result. (If `bind1st` had been used, the functor would perform `1.3 - x` instead.

Creator-wrapper functions like `bind1st` are intended to be used in calling algorithms. Their return values will be temporary objects. (The goal is to not require you to type names like `std::binder1st<std::plus<int>>` for declaring a variable to hold the return value from `bind1st(std::plus<int>(), 5)`).

These become more useful when combined with the composition functions.

These functions are deprecated in C++11 and can be replaced by `std::bind` (or `std::tr1::bind`) which is more powerful and flexible, supporting functions with any number of arguments. Uses of `bind1st` can be replaced by `std::bind(f, x, std::placeholders::_1)` and `bind2nd` by `std::bind(f, std::placeholders::_1, x)`.

3.24 Containers

Collaboration diagram for Containers:

Modules

- [Associative](#)
- [Sequences](#)
- [Unordered Associative](#)

3.24.1 Detailed Description

Containers are collections of objects.

A container may hold any type which meets certain requirements, but the type of contained object is chosen at compile time, and all objects in a given container must be of the same type. (Polymorphism is possible by declaring a container of pointers to a base class and then populating it with pointers to instances of derived classes. Variant value types such as the `any` class from `Boost` can also be used.

All contained types must be `Assignable` and `CopyConstructible`. Specific containers may place additional requirements on the types of their contained objects.

Containers manage memory allocation and deallocation themselves when storing your objects. The objects are destroyed when the container is itself destroyed. Note that if you are storing pointers in a container, `delete` is *not* automatically called on the pointers before destroying them.

All containers must meet certain requirements, summarized in `tables`.

The standard containers are further refined into [Sequences](#) and [Associative Containers](#). [Unordered Associative Containers](#).

3.31.1 Detailed Description

Classes and functions for reporting errors via exception classes.

3.31.2 Typedef Documentation

3.31.2.1 `typedef void(* std::terminate_handler) ()`

If you write a replacement terminate handler, it must be of this type.

Definition at line 89 of file exception.

3.31.2.2 `typedef void(* std::unexpected_handler) ()`

If you write a replacement unexpected handler, it must be of this type.

Definition at line 92 of file exception.

3.31.3 Function Documentation

3.31.3.1 `void __gnu_cxx::__verbose_terminate_handler ()`

A replacement for the standard `terminate_handler` which prints more information about the terminating exception (if any) on `stderr`.

Call

```
std::set_terminate(__gnu_cxx::__verbose_terminate_handler
)
```

to use. For more info, see <http://gcc.gnu.org/onlinedocs/libstdc++/manual/bk01pt02ch06s02.html>.

In 3.4 and later, this is on by default.

3.31.3.2 `template<typename _Ex> exception_ptr std::copy_exception (_Ex __ex) [noexcept]`

Obtain an `exception_ptr` pointing to a copy of the supplied object. This function is deprecated, use `std::make_exception_ptr` instead.

Definition at line 197 of file `exception_ptr.h`.

Referenced by `std::make_exception_ptr()`.

3.31.3.3 `exception_ptr std::current_exception () [noexcept]`

Obtain an `exception_ptr` to the currently handled exception. If there is none, or the currently handled exception is foreign, return the null value.

Referenced by `std::make_exception_ptr()`.

3.31.3.4 `terminate_handler std::get_terminate () [noexcept]`

Return the current terminate handler.

3.31.3.5 `unexpected_handler std::get_unexpected () [noexcept]`

Return the current unexpected handler.

3.31.3.6 `template<typename _Ex > exception_ptr std::make_exception_ptr (_Ex __ex) [noexcept]`

Obtain an `exception_ptr` pointing to a copy of the supplied object.

Definition at line 171 of file `exception_ptr.h`.

References `std::copy_exception()`, and `std::current_exception()`.

3.31.3.7 `void std::rethrow_exception (exception_ptr)`

Throw the object pointed to by the `exception_ptr`.

3.31.3.8 `template<typename _Ex > void std::rethrow_if_nested (const _Ex & __ex) [inline]`

If `__ex` is derived from `nested_exception`, `__ex.rethrow_nested()`.

Definition at line 153 of file `nested_exception.h`.

References `std::__addressof()`.

3.31.3.9 `terminate_handler std::set_terminate (terminate_handler) [noexcept]`

Takes a new handler function as an argument, returns the old function.

3.31.3.10 `unexpected_handler std::set_unexpected (unexpected_handler) [noexcept]`

Takes a new handler function as an argument, returns the old function.

3.31.3.11 `void std::terminate () [noexcept]`

The runtime will call this function if exception handling must be abandoned for any reason. It can also be called by the user.

3.31.3.12 `template<typename _Tp > void std::throw_with_nested (_Tp && __t) [inline]`

If `__t` is derived from `nested_exception`, throws `__t`. Else, throws an implementation-defined object derived from both.

Definition at line 116 of file `nested_exception.h`.

3.31.3.13 `bool std::uncaught_exception () [noexcept]`

[18.6.4]/1: 'Returns true after completing evaluation of a throw-expression until either completing initialization of the exception-declaration in the matching handler or entering `unexpected()` due to the throw; or after entering `terminate()` for any reason other than an explicit call to `terminate()`. [Note: This includes stack unwinding [15.2]. end note]'

2: 'When `uncaught_exception()` is true, throwing an exception can result in a call of `terminate()` (15.5.1).'

3.31.3.14 `int std::uncaught_exceptions () [noexcept]`

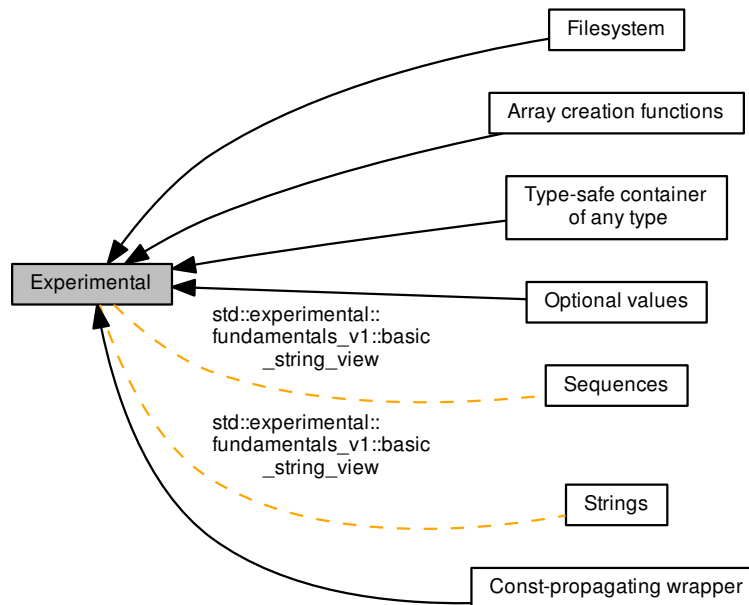

The number of uncaught exceptions.

3.31.3.15 `void std::unexpected ()`

The runtime will call this function if an exception is thrown which violates the function's exception specification.

3.35.1 Detailed Description

Function objects, or *functors*, are objects with an `operator()` defined and accessible. They can be passed as arguments to algorithm templates and used in place of a function pointer. Not only is the resulting expressiveness of the library increased, but the generated code can be more efficient than what you might write by hand. When we refer to *functors*, then, generally we include function pointers in the description as well.

Often, functors are only created as temporaries passed to algorithm calls, rather than being created as named variables.

Two examples taken from the standard itself follow. To perform a by-element addition of two vectors `a` and `b` containing `double`, and put the result in `a`, use

```
transform (a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

To negate every element in `a`, use

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

The addition and negation functions will be inlined directly.

The standard functors are derived from structs named `unary_function` and `binary_function`. These two classes contain nothing but typedefs, to aid in generic (template) programming. If you write your own functors, you might consider doing the same.

3.35.2 Function Documentation

3.35.2.1 `template<typename _Tp, typename _Class > _Mem_fn< _Tp _Class::* > std::mem_fn (_Tp _Class::* __pm) [inline], [noexcept]`

Returns a function object that forwards to the member pointer `pm`.

3.41.1 Detailed Description

Nearly all of the I/O classes are parameterized on the type of characters they read and write. (The major exception is `ios_base` at the top of the hierarchy.) This is a change from pre-Standard streams, which were not templates.

For ease of use and compatibility, all of the `basic_*` I/O-related classes are given typedef names for both of the builtin character widths (wide and narrow). The typedefs are the same as the pre-Standard names, for example:

```
1 typedef basic_ifstream<char> ifstream;
```

Because properly forward-declaring these classes can be difficult, you should not do it yourself. Instead, include the `<iosfwd>` header, which contains only declarations of all the I/O classes as well as the typedefs. Trying to forward-declare the typedefs themselves (e.g., `class ostream;`) is not valid ISO C++.

For more specific declarations, see <https://gcc.gnu.org/onlinedocs/libstdc++/manual/io.html#std.io.objects>

These are empty types, used to distinguish different iterators. The distinction is not made by what they contain, but simply by what they are. Different underlying algorithms can then be used based on the different operations supported by different iterator types.

3.44.1 Detailed Description

Abstractions for uniform iterating through various underlying types.

3.44.2 Function Documentation

3.44.2.1 `template<typename _Iter > iterator_traits<_Iter>::iterator_category std::__iterator_category (const _Iter &)`
`[inline]`

This function is not a part of the C++ standard but is syntactic sugar for internal library use only.

Definition at line 204 of file `stl_iterator_base_types.h`.

Referenced by `__gnu_debug::__check_string()`, `std::__find_if()`, `std::__find_if_not()`, `__gnu_debug::__get_distance()`, `std::__search_n_aux()`, `std::advance()`, `std::copy_n()`, `std::distance()`, `std::find_end()`, `std::includes()`, `std::next__↵` `permutation()`, `std::partition()`, `std::reverse()`, `std::_V2::rotate()`, `std::uninitialized_copy_n()`, and `std::unique_copy()`.

3.44.2.2 `template<typename _Container > back_insert_iterator<_Container> std::back_inserter (_Container & __x)`
`[inline]`

Parameters

<code>__↵</code>	A container of arbitrary type.
<code>__x</code>	

Returns

An instance of `back_insert_iterator` working on `__x`.

This wrapper function helps in creating `back_insert_iterator` instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 527 of file `bits/stl_iterator.h`.

Referenced by `std::match_results<_Bi_iter>::format()`, `std::operator>>()`, and `std::regex_replace()`.

3.44.2.3 `template<typename _Container> front_insert_iterator<_Container> std::front_inserter (_Container & __x)`
`[inline]`

Parameters

<code>__x</code>	A container of arbitrary type.
------------------	--------------------------------

Returns

An instance of `front_insert_iterator` working on `x`.

This wrapper function helps in creating `front_insert_iterator` instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 618 of file `bits/stl_iterator.h`.

3.44.2.4 `template<typename _Container, typename _Iterator> insert_iterator<_Container> std::inserter (_Container & __x,`
`_Iterator __i) [inline]`

Parameters

<code>__x</code>	A container of arbitrary type.
------------------	--------------------------------

Returns

An instance of `insert_iterator` working on `__x`.

This wrapper function helps in creating `insert_iterator` instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Parameters

<code>__x</code>	A <code>reverse_iterator</code> .

3.46.2 Function Documentation

3.46.2.1 `template<typename _Facet> bool std::has_facet (const locale & __loc) throw`

Test for the presence of a facet.

`has_facet` tests the locale argument for the presence of the facet type provided as the template parameter. Facets derived from the facet parameter will also return true.

Template Parameters

<code>_Facet</code>	The facet type to test the presence of.
---------------------	---

Parameters

<code>__loc</code>	The locale to test.
--------------------	---------------------

Returns

true if `__loc` contains a facet of type `_Facet`, else false.

Definition at line 104 of file `locale_classes.tcc`.

3.46.2.2 `template<typename _Facet> const _Facet & std::use_facet (const locale & __loc)`

Return a facet.

`use_facet` looks for and returns a reference to a facet of type `Facet` where `Facet` is the template parameter. If `has_facet(locale)` is true, there is a suitable facet to return. It throws `std::bad_cast` if the locale doesn't contain a facet of type `Facet`.

Template Parameters

<code>_Facet</code>	The facet type to access.
---------------------	---------------------------

Parameters

<code>__loc</code>	The locale to use.
--------------------	--------------------

Returns

Reference to facet of type `Facet`.

Exceptions

<code>std::bad_cast</code>	if <code>__loc</code> doesn't contain a facet of type <code>_Facet</code> .
----------------------------	---

3.47.1 Detailed Description

A collection of advanced mathematical special functions, defined by ISO/IEC IS 29124.

3.47.2 Function Documentation

3.47.2.1 `template<typename _Tp> __gnu_cxx::__promote<_Tp>::__type std::assoc_laguerre (unsigned int __n, unsigned int __m, _Tp __x) [inline]`

Return the associated Laguerre polynomial of nonnegative order n , nonnegative degree m and real argument $x \leftarrow$: $L_n^m(x)$.

The associated Laguerre function of real degree α , $L_n^\alpha(x)$, is defined by

$$L_n^\alpha(x) = \frac{(\alpha+1)_n}{n!} {}_1F_1(-n; \alpha+1; x)$$

where $(\alpha)_n$ is the Pochhammer symbol and ${}_1F_1(a; c; x)$ is the confluent hypergeometric function.

The associated Laguerre polynomial is defined for integral degree $\alpha = m$ by:

$$L_n^m(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x)$$

where the Laguerre polynomial is defined by:

$$L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x})$$

and $x \geq 0$.

See also

`laguerre` for details of the Laguerre function of degree n

Template Parameters

Return the associated Legendre function of degree `l` and order `m`.

The associated Legendre function is derived from the Legendre function $P_l(x)$ by the Rodrigues formula:

$$P_l^m(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_l(x)$$

3.51.1 Detailed Description

3.51.2 Function Documentation

3.51.2.1 `template<typename _II, typename _OI> _OI std::copy (_II __first, _II __last, _OI __result) [inline]`

Copies the range [first,last) into result.

Parameters

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.

Returns

`result + (first - last)`

This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling). Result may not be contained within [first,last); the `copy_backward` function should be used instead.

Note that the end of the output range is permitted to be contained within [first,last).

Definition at line 446 of file `stl_algobase.h`.

3.51.2.2 `template<typename _BI1, typename _BI2> _BI2 std::copy_backward (_BI1 __first, _BI1 __last, _BI2 __result) [inline]`

Copies the range [first,last) into result.

Parameters

<code>__first</code>	A bidirectional iterator.
<code>__last</code>	A bidirectional iterator.
<code>__result</code>	A bidirectional iterator.

Returns

`result - (first - last)`

The function has the same effect as `copy`, but starts at the end of the range and works its way to the start, returning the start of the result. This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Result may not be in the range (first,last]. Use `copy` instead. Note that the start of the output range may overlap [first,last).

Definition at line 622 of file `stl_algobase.h`.

3.51.2.3 `template<typename _InputIterator, typename _OutputIterator, typename _Predicate > _OutputIterator std::copy_if (`
`_InputIterator __first, _InputIterator __last, _OutputIterator __result, _Predicate __pred)`

Copy the elements of a sequence for which a predicate is true.

Parameters

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.
<code>__pred</code>	A predicate.

Returns

An iterator designating the end of the resulting sequence.

Copies each element in the range `[__first,__last)` for which `__pred` returns true to the range beginning at `__result`.

`copy_if()` is stable, so the relative order of elements that are copied is unchanged.

Definition at line 734 of file `stl_algo.h`.

3.51.2.4 `template<typename _InputIterator, typename _Size, typename _OutputIterator > _OutputIterator std::copy_n (`
`_InputIterator __first, _Size __n, _OutputIterator __result) [inline]`

Copies the range `[first,first+n)` into `[result,result+n)`.

Parameters

<code>__first</code>	An input iterator.
<code>__n</code>	The number of elements to copy.
<code>__result</code>	An output iterator.

Returns

`result+n`.

This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Definition at line 796 of file `stl_algo.h`.

References `std::__iterator_category()`.

3.51.2.5 `template<typename _ForwardIterator, typename _Tp > void std::fill (_ForwardIterator __first, _ForwardIterator __last,`

Parameters

<code>__first</code>	A forward iterator.
<code>__last</code>	A forward iterator.
<code>__value</code>	A reference-to-const of arbitrary type.

Returns

Nothing.

This function fills a range with copies of the same value. For char types filling contiguous areas of memory, this becomes an inline call to `memset` or `wmemset`.

Definition at line 724 of file `stl_algobase.h`.

```
3.51.2.6 template<typename _OI, typename _Size, typename _Tp> _OI std::fill_n ( _OI __first, _Size __n, const _Tp & __value )

Parameters

<code>__first</code>	An output iterator.
<code>__n</code>	The count of copies to perform.
<code>__value</code>	A reference-to-const of arbitrary type.

Returns

The iterator at `first+n`.

The ranges `[__first, __last)` and `[__result, __result+(__last-__first))` must not overlap.

Definition at line 1204 of file `stl_algo.h`.

<code>__first</code>	A forward iterator.
<code>__last</code>	A forward iterator.

Returns

An iterator designating the end of the resulting sequence.

Removes all but the first element from each group of consecutive values that compare equal. `unique()` is stable, so the relative order of elements that are not removed is unchanged. Elements between the end of the resulting sequence and `__last` are still present, but their value is unspecified.

3.51.2.34 `template<typename _ForwardIterator, typename _BinaryPredicate > _ForwardIterator std::unique (_ForwardIterator __first, _ForwardIterator __last, _BinaryPredicate __binary_pred)` `[inline]`

Remove consecutive values from a sequence using a predicate.

Parameters

<code>__first</code>	A forward iterator.
<code>__last</code>	A forward iterator.
<code>__binary_pred</code>	A binary predicate.

Returns

An iterator designating the end of the resulting sequence.

Removes all but the first element from each group of consecutive values for which `__binary_pred` returns true.

`unique()` is stable, so the relative order of elements that are not removed is unchanged. Elements between the end of the resulting sequence and `__last` are still present, but their value is unspecified.

3.51.2.35 `template<typename _InputIterator, typename _OutputIterator> _OutputIterator std::unique_copy (_InputIterator __first, _InputIterator __last, _OutputIterator __result) [inline]`

Copy a sequence, removing consecutive duplicate values.

Parameters

<code>__first</code>	An input iterator.
<code>__last</code>	An input iterator.
<code>__result</code>	An output iterator.

Returns

An iterator designating the end of the resulting sequence.

Copies each element in the range `[__first, __last)` to the range beginning at `__result`, except that only the first element is copied from groups of consecutive elements that compare equal. `unique_copy()` is stable, so the relative order of elements that are copied is unchanged.

- `template<typename _Predicate>`
`_GLIBCXX14_CONSTEXPR binary_negate<_Predicate> std::not2 (const _Predicate &__pred)`

3.53.1 Detailed Description

The functions `not1` and `not2` each take a predicate functor and return an instance of `unary_negate` or `binary_negate`, respectively. These classes are functors whose `operator()` performs the stored predicate function and then returns the negation of the result.

For example, given a vector of integers and a trivial predicate,

```

struct IntGreaterThanThree
: public std::unary_function<int, bool>
{
    bool operator() (int x) { return x > 3; }
};

std::find_if (v.begin(), v.end(), not1(IntGreaterThanThree()));
  
```

The call to `find_if` will locate the first index (*i*) of *v* for which `!(v[i] > 3)` is true.

The `not1/unary_negate` combination works on predicates taking a single argument. The `not2/binary_negate` combination works on predicates which take two arguments.

Because the sub-sequence must lie completely within the range `[__first1, __last1)` it must start at a position less than `__last1 - (__last2 - __first2)` where `__last2 - __first2` is the length of the sub-sequence. This means that the returned iterator `i` will be in the range `[__first1, __last1 - (__last2 - __first2))`.

An overload that attempts to take the address of an lvalue as a constant expression. Falls back to `__addressof` in the presence of an overloaded `addressof` operator (unary operator`&`), in which case the call will not be a constant expression.

Returns

A `shared_ptr` that owns the newly created object.

Exceptions

<i>An</i>	exception thrown from <code>_Alloc::allocate</code> or from the constructor of <code>_Tp</code> .
-----------	---

A copy of `__a` will be used to allocate memory for the `shared_ptr` and the new object.

3.64.1 Detailed Description

These classes define objects which provide random or pseudorandom numbers, either from a discrete or a continuous interval. The random number generator supplied as a part of this library are all uniform random number generators which provide a sequence of random number uniformly distributed over their range.

A number generator is a function object with an `operator()` that takes zero arguments and returns a number.

A compliant random number generator must satisfy the following requirements.

3.68.1 Detailed Description

Because libstdc++ based its implementation of the STL subsections of the library on the SGI 3.3 implementation, we inherited their extensions as well.

They are additionally documented in the [online documentation](#), a copy of which is also shipped with the library source code (in `.../docs/html/documentation.html`). You can also read the documentation [on SGI's site](#), which is still running even though the code is not maintained.

NB that the following notes are pulled from various comments all over the place, so they may seem stilted.

The `identity_element` functions are not part of the C++ standard; SGI provided them as an extension. Its argument is an operation, and its return value is the identity element for that operation. It is overloaded for addition and multiplication, and you can overload it for your own nefarious operations.

As an extension to the binders, SGI provided composition functors and wrapper functions to aid in their creation. The `unary_compose` functor is constructed from two functions/functors, `f` and `g`. Calling `operator()` with a single argument `x` returns `f(g(x))`. The function `compose1` takes the two functions and constructs a `unary_compose` variable for you.

`binary_compose` is constructed from three functors, `f`, `g1`, and `g2`. Its `operator()` returns `f(g1(x),g2(x))`. The function `compose2` takes `f`, `g1`, and `g2`, and constructs the `binary_compose` instance for you. For example, if `f` returns an `int`, then

```
int answer = (compose2(f,g1,g2))(x);
```

is equivalent to

```
int temp1 = g1(x);
int temp2 = g2(x);
int answer = f(temp1,temp2);
```

But the first form is more compact, and can be passed around as a functor to other algorithms.

As an extension, SGI provided a functor called `identity`. When a functor is required but no operations are desired, this can be used as a pass-through. Its `operator()` returns its argument unchanged.

`select1st` and `select2nd` are extensions provided by SGI. Their `operator()`s take a `std::pair` as an argument, and return either the first member or the second member, respectively. They can be used (especially with the composition functors) to *strip* data from a sequence before performing the remainder of an algorithm.

The `operator()` of the `project1st` functor takes two arbitrary arguments and returns the first one, while `project2nd` returns the second one. They are extensions provided by SGI.

These three functors are each constructed from a single arbitrary variable/value. Later, their `operator()`s completely ignore any arguments passed, and return the stored value.

- `constant_void_fun`'s `operator()` takes no arguments
- `constant_unary_fun`'s `operator()` takes one argument (ignored)
- `constant_binary_fun`'s `operator()` takes two arguments (ignored)

The helper creator functions `constant0`, `constant1`, and `constant2` each take a *result* argument and construct variables of the appropriate functor type.

3.68.2 Function Documentation

3.68.2.1 `template<typename _Tp> const _Tp& __gnu_cxx::__median (const _Tp & __a, const _Tp & __b, const _Tp & __c)`

Find the median of three values.

Parameters

\leftrightarrow _a	A value.
\leftrightarrow _b	A value.
\leftrightarrow _c	A value.

Returns

One of a, b or c.

If $\{1,m,n\}$ is some convolution of $\{a,b,c\}$ such that $1 \leq m \leq n$ then the value returned will be m. This is an SGI extension.

Definition at line 546 of file ext/algorithm.

3.68.2.2 `template<typename _Tp, typename _Compare> const _Tp& __gnu_cxx::__median (const _Tp & __a, const _Tp & __b, const _Tp & __c, _Compare __comp)`

Find the median of three values using a predicate for comparison.

Parameters

__a	A value.
__b	A value.
__c	A value.
__comp	A binary predicate.

Returns

One of a, b or c.

If $\{1,m,n\}$ is some convolution of $\{a,b,c\}$ such that `comp (1, m)` and `comp (m, n)` are both true then the value returned will be m. This is an SGI extension.

        __gnu_cxx::copy_n ( _InputIterator __first, _Size __count, _OutputIterator __result )  [inline]
```

Copies the range `[first,first+count)` into `[result,result+count)`.

Parameters

<code>__first</code>	An input iterator.
<code>__count</code>	The number of elements to copy.
<code>__result</code>	An output iterator.

Returns

A `std::pair` composed of `first+count` and `result+count`.

This is an SGI extension. This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

- class `std::stack<_Tp, _Sequence>`
- class `std::vector<_Tp, _Alloc>`
- class `std::vector<bool, _Alloc>`

3.69.1 Detailed Description

Sequences arrange a collection of objects into a strictly linear order.

The differences between sequences are usually due to one or both of the following:

- memory management
- algorithmic complexity

As an example of the first case, `vector` is required to use a contiguous memory layout, while other sequences such as `deque` are not.

The prime reason for choosing one sequence over another should be based on the second category of differences, algorithmic complexity. For example, if you need to perform many inserts and removals from the middle of a sequence, `list` would be ideal. But if you need to perform constant-time access to random elements of the sequence, then `list` should not be used.

All sequences must meet certain requirements, summarized in [tables](#).

3.70.1 Detailed Description

These algorithms are common set operations performed on sequences that are already sorted. The number of comparisons will be linear.

3.70.2 Function Documentation

3.70.2.1 `template<typename _InputIterator1, typename _InputIterator2 > bool std::includes (_InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2) [inline]`

Determines whether all elements of a sequence exists in a range.

Parameters

<code>__first1</code>	Start of search range.
<code>__last1</code>	End of search range.
<code>__first2</code>	Start of sequence
<code>__last2</code>	End of sequence.

Returns

True if each element in `[__first2,__last2)` is contained in order within `[__first1,__last1)`. False otherwise.

This operation expects both `[__first1,__last1)` and `[__first2,__last2)` to be sorted. Searches for the presence of each element in `[__first2,__last2)` within `[__first1,__last1)`. The iterators over each range only move forward, so this is a linear algorithm. If an element in `[__first2,__last2)` is not found before the search iterator reaches `__last2`, false is returned.

Definition at line 2823 of file `stl_algo.h`.

3.70.2.2 `template<typename _InputIterator1, typename _InputIterator2, typename _Compare > bool std::includes (_InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2, _Compare __comp) [inline]`

Determines whether all elements of a sequence exists in a range using comparison.

Parameters

<code>__first1</code>	Start of search range.
<code>__last1</code>	End of search range.
<code>__first2</code>	Start of sequence
<code>__last2</code>	End of sequence.
<code>__comp</code>	Comparison function to use.

Returns

True if each element in `[__first2,__last2)` is contained in order within `[__first1,__last1)` according to `comp`. False otherwise.

This operation expects both `[__first1,__last1)` and `[__first2,__last2)` to be sorted. Searches for the presence of each element in `[__first2,__last2)` within `[__first1,__last1)`, using `comp` to decide. The iterators over each range only move forward, so this is a linear algorithm. If an element in `[__first2,__last2)` is not found before the search iterator reaches `__last2`, false is returned.

std::set_difference ( _InputIterator1 __first1, _InputIterator1 __last1, _InputIterator2 __first2, _InputIterator2 __last2,
    _OutputIterator __result ) [inline]
```

Return the difference of two sorted ranges.

Parameters

<code>__first1</code>	Start of first range.
<code>__last1</code>	End of first range.
<code>__first2</code>	Start of second range.
<code>__last2</code>	End of second range.

Returns

End of the output range.

This operation iterates over both ranges, copying elements present in the first range but not the second in order to the output range. Iterators increment for each range. When the current element of the first range is less than the second, that element is copied and the iterator advances. If the current element of the second range is less, the iterator advances, but no element is copied. If an element is contained in both ranges, no elements are copied and both ranges advance. ```

Return the difference of two sorted ranges using comparison functor.

Parameters

Parameters

3.71.1 Detailed Description

3.71.2 Function Documentation

3.71.2.1 `template<typename _BidirectionalIterator > void std::inplace_merge (_BidirectionalIterator __first, _BidirectionalIterator __middle, _BidirectionalIterator __last) [inline]`

Merges two sorted ranges in place.

Parameters

<code>__first</code>	An iterator.
<code>__middle</code>	Another iterator.
<code>__last</code>	Another iterator.

Returns

Nothing.

Merges two sorted and consecutive ranges, `[__first, __middle)` and `[__middle, __last)`, and puts the result in `[__first, __last)`. The output will be sorted. The sort is *stable*, that is, for equivalent elements in the two ranges, elements from the first range will always come before elements from the second.

If enough additional memory is available, this takes $(\text{__last} - \text{__first}) - 1$ comparisons. Otherwise an $N \log N$ algorithm is used, where N is `distance(__first, __last)`.

```
3.71.2.35 template<typename _RandomAccessIterator> void std::stable_sort ( _RandomAccessIterator __first,
    _RandomAccessIterator __last ) [inline]
```

Sort the elements of a sequence, preserving the relative order of equivalent elements.

Parameters

<code>__first</code>	An iterator.
<code>__last</code>	Another iterator.

Returns

Nothing.

Sorts the elements in the range $[_first, _last)$ in ascending order, such that for each iterator i in the range $[_first, _last-1)$, $*(i+1) < *i$ is false.

The relative ordering of equivalent elements is preserved, so any two elements x and y in the range $[_first, _last)$ such that $x < y$ is false and $y < x$ is false will have the same relative ordering after calling `stable_sort()`.

3.71.2.36 `template<typename _RandomAccessIterator, typename _Compare> void std::stable_sort (_RandomAccessIterator
__first, _RandomAccessIterator __last, _Compare __comp) [inline]`

Sort the elements of a sequence using a predicate for comparison, preserving the relative order of equivalent elements.

Parameters

<code>__first</code>	An iterator.
<code>__last</code>	Another iterator.
<code>__comp</code>	A comparison functor.

Returns

Nothing.

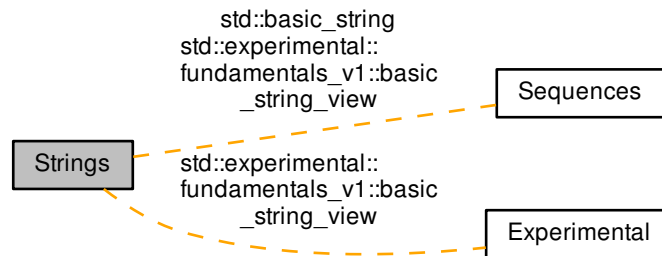

Sorts the elements in the range $[_first, _last)$ in ascending order, such that for each iterator i in the range $[_first, _last-1)$, `__comp(*(i+1),*i)` is false.

The relative ordering of equivalent elements is preserved, so any two elements x and y in the range $[_first, _last)$ such that `__comp(x, y)` is false and `__comp(y, x)` is false will have the same relative ordering after calling `stable_sort()`.

3.79.1 Detailed Description

Unordered associative containers allow fast retrieval of data based on keys.

Each container type is parameterized on a `Key` type, a `Hash` type providing a hashing functor, and an ordering relation used to sort the elements of the container.

All unordered associative containers must meet certain requirements, summarized in [tables](#).

Parameters

<code>_↵ _x</code>	The first object.
<code>_↵ _y</code>	The second object.

4.1.1 Detailed Description

GNU extensions for public use.

4.1.2 Function Documentation

4.1.2.1 `template<typename _ToType, typename _FromType > _ToType __gnu_cxx::__static_pointer_cast (const _FromType & __arg) [inline]`

Casting operations for cases where `_FromType` is not a standard pointer. `_ToType` can be a standard or non-standard pointer. Given that `_FromType` is not a pointer, it must have a `get()` method that returns the standard pointer equivalent of the address it points to, and must have an `element_type` typedef which names the type it points to.

Definition at line 68 of file `cast.h`.

4.1.2.2 `template<typename _ToType, typename _FromType > _ToType __gnu_cxx::__static_pointer_cast (_FromType * __arg) [inline]`

Casting operations for cases where `_FromType` is a standard pointer. `_ToType` can be a standard or non-standard pointer.

Definition at line 96 of file `cast.h`.

4.1.2.3 `size_t __gnu_cxx::Bit_scan_forward (size_t __num) [inline]`

Variables

- `static const int _CASable_bits`
- `static const _CASable _CASable_mask`

4.6.1 Detailed Description

GNU parallel code for public use.

4.6.2 Typedef Documentation

4.6.2.1 `typedef unsigned short __gnu_parallel::_BinIndex`

Type to hold the index of a bin.

Since many variables of this type are allocated, it should be chosen as small as possible.

Definition at line 47 of file `random_shuffle.h`.

4.6.2.2 `typedef int64_t __gnu_parallel::_CASable`

Longest compare-and-swappable integer type on this platform.

Definition at line 127 of file `types.h`.

4.6.2.3 `typedef uint64_t __gnu_parallel::_SequenceIndex`

Unsigned integer to index `__elements`. The total number of elements for each algorithm must fit into this type.

Definition at line 117 of file `types.h`.

4.6.2.4 `typedef uint16_t __gnu_parallel::_ThreadIndex`

Unsigned integer to index a thread number. The maximum thread number (for each processor) must fit into this type.

Definition at line 123 of file `types.h`.

4.6.3 Enumeration Type Documentation

4.6.3.1 `enum __gnu_parallel::_AlgorithmStrategy`

Strategies for run-time algorithm selection:

Definition at line 67 of file `types.h`.

4.6.3.2 enum `__gnu_parallel::_FindAlgorithm`

Find algorithms:

Definition at line 106 of file types.h.

4.6.3.3 enum `__gnu_parallel::_MultiwayMergeAlgorithm`

Merging algorithms:

4.6.3.4 enum `__gnu_parallel::_Parallelism`

Run-time equivalents for the compile-time tags.

Enumerator

sequential Not parallel.

parallel_unbalanced Parallel unbalanced (equal-sized chunks).

parallel_balanced Parallel balanced (work-stealing).

parallel_omp_loop Parallel with OpenMP dynamic load-balancing.

parallel_omp_loop_static Parallel with OpenMP static load-balancing.

parallel_taskqueue Parallel with OpenMP taskqueue construct.

Definition at line 44 of file types.h.

4.6.3.5 enum `__gnu_parallel::_PartialSumAlgorithm`

Partial sum algorithms: recursive, linear.

Sorting/merging algorithms: sampling, `__exact`.

Definition at line 98 of file types.h.

4.6.4 Function Documentation

4.6.4.1 `template<typename _RAIter, typename _DifferenceTp> void __gnu_parallel::_calc_borders (_RAIter __elements, _DifferenceTp __length, _DifferenceTp * __off)`

Precalculate `__advances` for Knuth-Morris-Pratt algorithm.

Parameters

<code>__elements</code>	Begin iterator of sequence to search for.
<code>__length</code>	Length of sequence to search for.
<code>__off</code>	Returned <code>__offsets</code> .

4.6.4.2 `template<typename _Tp> bool __gnu_parallel::__compare_and_swap (volatile _Tp * __ptr, _Tp __comparand, _Tp __replacement) [inline]`

Compare-and-swap.

Compare `*__ptr` and `__comparand`. If equal, let `*__ptr=__replacement` and return true, return false otherwise.

Parameters

<code>__ptr</code>	Pointer to signed integer.
<code>__comparand</code>	Compare value.

4.6.4.3 `void __gnu_parallel::__decode2 (_CASable __x, int & __a, int & __b) [inline]`

Decode two integers from one `gnu_parallel::CASable`.

Parameters

<code>↵ __x</code>	<code>__gnu_parallel::CASable</code> to decode integers from.
<code>↵ __a</code>	First integer, to be decoded from the most-significant <code>_CASable_bits/2</code> bits of <code>__x</code> .

```

Multiway Merge Frontend.

Merge the sequences specified by `seqs_begin` and `__seqs_end` into `__target`. `__seqs_begin` and `__seqs_end` must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the `_M_end` of the same sequence in their second entry.

Ties are broken arbitrarily. See `stable_multiway_merge` for a variant that breaks ties by sequence number but is slower.

The first entries of the pairs (i.e. the begin iterators) will be moved forward.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- not using sentinels

Example:

```
int sequences[10][10];
for (int __i = 0; __i < 10; ++__i)
    for (int __j = 0; __j < 10; ++__j)
        sequences[__i][__j] = __j;

int __out[33];
std::vector<std::pair<int*> > seqs;
for (int __i = 0; __i < 10; ++__i)
    { seqs.push(std::make_pair<int*>(sequences[__i],
                                    sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int>(), 33);
```

Precondition

All input sequences must be sorted.

<code>_RAIterOut</code>	iterator over target sequence
<code>_DifferenceTp</code>	difference type for the sequence
<code>_Compare</code>	strict weak ordering type to compare elements in sequences

Highly efficient 3-way merging procedure.

Merging is done with the algorithm implementation described by Peter Sanders. Basically, the idea is to minimize the number of necessary comparison after merging an element. The implementation trick that makes this fast is that the order of the sequences is stored in the instruction pointer (translated into labels in C++).

This works well for merging up to 4 sequences.

Note that making the merging stable does *not* come at a performance hit.

Whether the merging is done guarded or unguarded is selected by the used iterator class.

Parameters

<code>__seqs_begin</code>	Begin iterator of iterator pair input sequence.
<code>__seqs_end</code>	End iterator of iterator pair input sequence.
<code>__target</code>	Begin iterator of output sequence.
<code>__comp</code>	Comparator.
<code>__length</code>	Maximum length to merge, less equal than the total number of elements available.

Returns

End iterator of output sequence.

Multiway Merge Frontend.

Merge the sequences specified by `seqs_begin` and `__seqs_end` into `__target`. `__seqs_begin` and `__seqs_end` must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the `_M_end` of the same sequence in their second entry.

Ties are broken arbitrarily. See `stable_multiway_merge` for a variant that breaks ties by sequence number but is slower.

The first entries of the pairs (i.e. the begin iterators) will be moved forward accordingly.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- using sentinels

You have to take care that the element the `_M_end` iterator points to is readable and contains a value that is greater than any other non-sentinel value in all sequences.

Example:

```

int sequences[10][11];
for (int __i = 0; __i < 10; ++__i)
    for (int __j = 0; __i < 11; ++__j)
        sequences[__i][__j] = __j; // __last one is sentinel!

int __out[33];
std::vector<std::pair<int*> > seqs;
for (int __i = 0; __i < 10; ++__i)
    { seqs.push(std::make_pair<int*>(sequences[__i],
                                    sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int>(), 33);

```

Precondition

All input sequences must be sorted.

Target must provide enough space to merge out length elements or the number of elements in all sequences, whichever is smaller.

For each `__i`, `__seqs_begin[__i].second` must be the end marker of the sequence, but also reference the one more `__sentinel` element.

Postcondition

[`__target`, return `__value`) contains merged `__elements` from the input sequences.
 return `__value` - `__target` = min(`__length`, number of elements in all sequences).

4.8.1 Detailed Description

GNU profile code for public use.

4.8.2 Typedef Documentation

4.8.2.1 `typedef std::unordered_map<std::string, std::string> __gnu_profile::__env_t`

Internal environment. Values can be set one of two ways: 1. In config file "var = value". The default config file path is `libstdc++-profile.conf`. 2. By setting process environment variables. For instance, in a Bash shell you can set the unit cost of iterating through a map like this: `export __map_iterate_cost_factor=5.0`. If a value is set both in the input file and through an environment variable, the environment value takes precedence.

Definition at line 65 of file `profiler_trace.h`.

4.8.3 Function Documentation

4.8.3.1 `bool __gnu_profile::__profcxx_init() [inline]`

This function must be called by each instrumentation point.

The common path is inlined fully.

Definition at line 653 of file `profiler_trace.h`.

4.8.3.2 `void __gnu_profile::__report() [inline]`

Final report method, registered with **atexit**.

This can also be called directly by user code, including signal handlers. It is protected against deadlocks by the reentrance guard in `profiler.h`. However, when called from a signal handler that triggers while within `__gnu_profile` (under the guarded zone), no output will be produced.

Definition at line 448 of file `profiler_trace.h`.

Master lock.

4.9 `__gnu_sequential` Namespace Reference

4.9.1 Detailed Description

GNU sequential classes for public use.

4.10 abi Namespace Reference

4.10.1 Detailed Description

The cross-vendor C++ Application Binary Interface. A namespace alias to `__cxxabiv1`, but user programs should use the alias 'abi'.

A brief overview of an ABI is given in the libstdc++ FAQ, question 5.8 (you may have a copy of the FAQ locally, or you can view the online version at http://gcc.gnu.org/onlinedocs/libstdc++/faq.html#5_8).

GCC subscribes to a cross-vendor ABI for C++, sometimes called the IA64 ABI because it happens to be the native ABI for that platform. It is summarized at <http://www.codesourcery.com/cxx-abi/> along with the current specification.

For users of GCC greater than or equal to 3.x, entry points are available in `<cxxabi.h>`, which notes, *'It is not normally necessary for user programs to include this header, or use the entry points directly. However, this header is available should that be needed.'*

Standard Stream Objects

The `<iostream>` header declares the eight standard stream objects. For other declarations, see <http://gcc.gnu.org/onlinedocs/libstdc++/manual/io.html> and the [I/O forward declarations](#)

They are required by default to cooperate with the global C library's `FILE` streams, and to be available during program startup and termination. For more information, see the section of the manual linked to above.

Parameters

4.11.4.82 `template<typename _MoneyT> _Get_money<_MoneyT> std::get_money (_MoneyT & __mon, bool __intl = false) [inline]`

Parameters

<code>__mon</code>	Either long double or a specialization of <code>basic_string</code> .

4.11.4.84 `template<typename _Tp> pair<_Tp*, ptrdiff_t> std::get_temporary_buffer (ptrdiff_t __len)` `[noexcept]`

Allocates a temporary buffer.

Parameters

<code>__len</code>	The number of objects of type <code>Tp</code> .
--------------------	---

Returns

See full description.

Reinventing the wheel, but this time with prettier spokes!

This function tries to obtain storage for `__len` adjacent `Tp` objects. The objects themselves are not constructed, of course. A `pair<>` is returned containing *the buffer's address and capacity (in the units of `sizeof(_Tp)`)*, or a pair of 0 values if no storage can be obtained. Note that the capacity obtained may be less than that requested if the memory is unavailable; you should compare `len` with the `.second` return value.

Provides the nothrow exception guarantee.

This manipulator uses `time_get::get` to extract time. `[ext.manip]`

Parameters

<code>__tmb</code>	struct to extract the time data to.
<code>__fmt</code>	format string.

```

Read a line from stream into a string.

Parameters

<code>__is</code>	Input stream.
<code>__str</code>	Buffer to store into.
<code>__delim</code>	Character marking end of line.

Returns

Reference to the input stream.

Stores characters from `__is` into `__str` until `__delim` is found, the end of the stream is encountered, or `str.max_size()` is reached. If `is.width()` is non-zero, that is the limit on the number of characters stored into `__str`. Any previous contents of `__str` are erased. Parameters

Returns

__in

Behaves like one of the formatted arithmetic extractors described in `std::basic_istream`. After constructing a sentry object with good status, this function extracts up to `n` characters and stores them into the array starting at `__s`. `n` is defined as:

- `n` is *the number of elements of the largest array of **
- *char_type that can store a terminating eos.*

Characters are extracted and stored until one of the following happens:

- `n-1` characters are stored

- EOF is reached
- the next character is whitespace according to the current locale
- the next character is a null byte (i.e., `charT()`)

4.11.4.297 `template<typename _CharT, typename _Traits> basic_istream< _CharT, _Traits> & std::ws (basic_istream< _CharT, _Traits> & __is)`

Quick and easy way to eat whitespace.

This manipulator extracts whitespace characters, stopping when the next character is non-whitespace, or when the input sequence is empty. If the sequence is empty, `eofbit` is set in the stream, but not `failbit`.

The current locale is used to distinguish whitespace characters.

Example:

```
MyClass mc;
std::cin >> std::ws >> mc;
```

will skip leading whitespace before calling `operator>>` on `cin` and your object. Note that the same effect can be achieved by creating a `std::basic_istream::sentry` inside your definition of `operator>>`.

<code>__l2</code>	Meets Mutex requirements (<code>try_lock()</code> may throw).
<code>__l3</code>	Meets Mutex requirements (<code>try_lock()</code> may throw).

Returns

Returns -1 if all `try_lock()` calls return true. Otherwise returns a 0-based index corresponding to the argument that returned false.

Postcondition

Either all arguments are locked, or none will be.

Sequentially calls `try_lock()` on each argument.

4.11.5.3 `__thread void* std::__once_callable`

Returns

Returns -1 if all `try_lock()` calls return true. Otherwise returns a 0-based index corresponding to the argument that returned false.

Postcondition

Either all arguments are locked, or none will be.

4.12.1 Detailed Description

GNU debug code, replaces standard behavior with debug behavior.

Macros and namespaces used by the implementation outside of debug wrappers to verify certain properties. The `__glibcxx_requires_xxx` macros are merely wrappers around the `__glibcxx_check_xxx` wrappers when we are compiling with debug mode, but disappear when we are in release mode so that there is no checking performed in, e.g., the standard library algorithms.

4.19.4.7 `constexpr syntax_option_type std::regex_constants::extended`

Specifies that the grammar recognized by the regular expression engine is that used by POSIX extended regular expressions in IEEE Std 1003.1-2001, Portable Operating System Interface (POSIX), Base Definitions and Headers, Section 9, Regular Expressions.

Definition at line 141 of file `regex_constants.h`.

Referenced by `std::regex_traits<_Ch_type>::getloc()`.

4.19.4.8 `constexpr match_flag_type std::regex_constants::format_default`

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the ECMAScript replace function in ECMA- 262 [Ecma International, ECMAScript Language Specification, Standard Ecma-262, third edition, 1999], part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression are located and replaced, and sections of the input that did not match the expression are copied unchanged to the output string.

Format strings (from ECMA-262 [15.5.4.11]):

- `$$` The dollar-sign itself (`$`)
- `$&` The matched substring.
- `$'` The portion of *string* that precedes the matched substring. This would be `match_results::prefix()`.
- `$'` The portion of *string* that follows the matched substring. This would be `match_results::suffix()`.
- `$n` The *n*th capture, where *n* is in [1,9] and `$n` is not followed by a decimal digit. If `n <= match_results::size()` and the *n*th capture is undefined, use the empty string instead. If `n > match_results::size()`, the result is implementation-defined.
- `$nn` The *nn*th capture, where *nn* is a two-digit decimal number on [01, 99]. If `nn <= match_results::size()` and the *n*th capture is undefined, use the empty string instead. If `nn > match_results::size()`, the result is implementation-defined.

Referenced by `std::match_results< _Bi_iter >::cend()`.

4.19.4.9 `constexpr match_flag_type std::regex_constants::format_first_only`

When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.

Definition at line 368 of file `regex_constants.h`.

Referenced by `std::regex_replace()`.

4.19.4.10 `constexpr match_flag_type std::regex_constants::format_no_copy`

During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.

Definition at line 361 of file `regex_constants.h`.

Referenced by `std::regex_replace()`.

4.19.4.11 constexpr match_flag_type std::regex_constants::format_sed

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the POSIX sed utility in IEEE Std 1003.1- 2001 [IEEE, Information Technology – Portable Operating System Interface (POSIX), IEEE Standard 1003.1-2001].

4.19.4.12 constexpr syntax_option_type std::regex_constants::grep

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility grep in IEEE Std 1003.1-2001. This option is identical to syntax_option_type basic, except that newlines are treated as whitespace.

Definition at line 161 of file regex_constants.h.

Referenced by std::regex_traits< _Ch_type >::getloc().

4.19.4.13 constexpr syntax_option_type std::regex_constants::icase

Referenced by std::regex_traits< _Ch_type >::getloc().

4.19.4.14 constexpr match_flag_type std::regex_constants::match_any

If more than one match is possible then any match is an acceptable result.

Definition at line 296 of file regex_constants.h.

4.19.4.15 constexpr match_flag_type std::regex_constants::match_continuous

The expression only matches a sub-sequence that begins at first .

4.19.4.17 constexpr match_flag_type std::regex_constants::match_not_bol

The first character in the sequence [first, last) is treated as though it is not at the beginning of a line, so the character (^) in the regular expression shall not match [first, first).

Definition at line 267 of file regex_constants.h.

4.19.4.18 constexpr match_flag_type std::regex_constants::match_not_bow

The expression \b is not matched against the sub-sequence [first,first).

Definition at line 282 of file regex_constants.h.

4.19.4.19 constexpr match_flag_type std::regex_constants::match_not_eol

The last character in the sequence [first, last) is treated as though it is not at the end of a line, so the character (\$) in the regular expression shall not match [last, last).

Definition at line 275 of file regex_constants.h.

4.19.4.20 constexpr match_flag_type std::regex_constants::match_not_eow

The expression \b should not be matched against the sub-sequence [last,last).

Referenced by std::regex_traits< _Ch_type >::getloc().

4.19.4.24 constexpr syntax_option_type std::regex_constants::optimize

Specifies that the regular expression engine should pay more attention to the speed with which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.

5.4.1 Detailed Description

```
template<typename _Tp>
class __gnu_cxx::__detail::__mini_vector< _Tp >
```

`__mini_vector<>` is a stripped down version of the full-fledged `std::vector<>`.

It is to be used only for built-in types or PODs. Notable differences are:

1. Not all accessor functions are present. 2. Used ONLY for PODs. 3. No Allocator template argument. Uses operator `new()` to get memory, and operator `delete()` to free it. Caveat: The dtor does NOT free the memory allocated, so this a memory-leaking vector!

5.14.1 Detailed Description

Base class for `__pool_alloc`.

Uses various allocators to fulfill underlying requests (and makes as few requests as possible when in default high-speed pool mode).

Important implementation properties: 0. If globally mandated, then allocate objects from new 1. If the clients request an object of size $> _S_max_bytes$, the resulting object will be obtained directly from new 2. In all other cases, we allocate an object of size exactly $_S_round_up(requested_size)$. Thus the client has enough size information that we can return the object to the proper free list without permanently losing part of the object.

5.16.1 Detailed Description

```
template<typename _CharT, typename _Traits, typename _Alloc>
class __gnu_cxx::__rc_string_base<_CharT, _Traits, _Alloc>
```

Documentation? What's that? Nathan Myers ncm@cantrip.org.

A string looks like this:

```

                                     [_Rep]
                                     _M_length
[ __rc_string_base<char_type>]      _M_capacity
_M_dataplus                       _M_refcount
_M_p ----->                     unnamed array of char_type
```

Where the `_M_p` points to the first character in the string, and you cast it to a pointer-to-`_Rep` and subtract 1 to get a pointer to the header.

This approach has the enormous advantage that a string object requires only one allocation. All the ugliness is confined within a single pair of inline functions, which each compile to a single *add* instruction: `_Rep::_M_refdata()`, and `__rc_string_base::_M_rep()`; and the allocation function which gets a block of raw bytes and with room enough and constructs a `_Rep` object at the front.

The reason you want `_M_data` pointing to the character array and not the `_Rep` is so that the debugger can see the string contents. (Probably we should add a non-inline member to get the `_Rep` for the debugger to use, so users can check the actual string length.)

Note that the `_Rep` object is a POD so that you can have a static *empty string* `_Rep` object already *constructed* before static constructors have run. The reference-count encoding is chosen so that a 0 indicates one reference, so you never try to destroy the empty-string `_Rep` object.

All but the last paragraph is considered pretty conventional for a C++ string implementation.

Remove characters.

Parameters

<code>__pos</code>	Index of first character to remove (default 0).
<code>__n</code>	Number of characters to remove (default remainder).

Returns

Reference to this string.

Exceptions

<code>std::out_of_range</code>	If <code>__pos</code> is beyond the end of this string.
--------------------------------	---

Removes `__n` characters from this string starting at `__pos`. The length of the string is reduced by `__n`. If there are `< __n` characters to remove, the remainder of the string is truncated. If `__p` is beyond end of string, `out_of_range` is thrown. The value of the string doesn't change if an error is thrown.

Remove one character.

Parameters

<code>__position</code>	Iterator referencing the character to remove.
-------------------------	---

Returns

iterator referencing same location after removal.

Removes the character at `__position` from this string. The value of the string doesn't change if an error is thrown.

Parameters

<code>__res_arg</code>	Number of characters required.
------------------------	--------------------------------

Exceptions

The advantage of this function is that if optimal code is a necessity and the user can determine the string length that will be required, the user can reserve the memory in advance, and thus prevent a possible reallocation of memory and copying of string data.

```
template<typename _ToType>
struct __gnu_cxx::_Caster<_ToType>

These functions are here to allow containers to support non standard pointer types. For normal pointers, these resolve to the use of the standard cast operation. For other types the functions will perform the appropriate cast to/from the custom pointer class so long as that class meets the following conditions: 1) has a typedef `element_type` which names the type it points to. 2) has a `get()` const method which returns `element_type*`. 3) has a constructor which can take one `element_type*` argument. This type supports the semantics of the pointer cast operators (below.)

5.23.1 Detailed Description

```
template<typename _Storage_policy>
class __gnu_cxx::_Pointer_adapter<_Storage_policy >
```

The following provides an 'alternative pointer' that works with the containers when specified as the pointer typedef of the allocator.

The pointer type used with the containers doesn't have to be this class, but it must support the implicit conversions, pointer arithmetic, comparison operators, etc. that are supported by this class, and avoid raising compile-time ambiguities. Because creating a working pointer can be challenging, this pointer template was designed to wrapper an easier storage policy type, so that it becomes reusable for creating other pointer types.

A key point of this class is also that it allows container writers to 'assume' `Allocator::pointer` is a typedef for a normal pointer. This class supports most of the conventions of a true pointer, and can, for instance handle implicit conversion to const and base class pointer types. The only impositions on container writers to support extended pointers are: 1) use the `Allocator::pointer` typedef appropriately for pointer types. 2) if you need pointer casting, use the `__pointer_cast<>` functions from `ext/cast.h`. This allows pointer cast operations to be overloaded as necessary by custom pointers.

Note: The const qualifier works with this pointer adapter as follows:

```
_Tp* == _Pointer_adapter<_Std_pointer_impl<_Tp> >; const _Tp* == _Pointer_adapter<_Std_pointer_impl<const
_Tp> >; _Tp* const == const _Pointer_adapter<_Std_pointer_impl<_Tp> >; const _Tp* const == const _Pointer_

5.24.1 Detailed Description

```
template<typename _Tp>
class __gnu_cxx::Relative_pointer_impl< _Tp >
```

A storage policy for use with `_Pointer_adapter<>` which stores the pointer's address as an offset value which is relative to its own address.

This is intended for pointers within shared memory regions which might be mapped at different addresses by different processes. For null pointers, a value of 1 is used. (0 is legitimate sometimes for nodes in circularly linked lists) This value was chosen as the least likely to generate an incorrect null, As there is no reason why any normal pointer would point 1 byte into its own pointer address.

```
template<typename _Tp>
class __gnu_cxx::Std_pointer_impl<_Tp>

A storage policy for use with `_Pointer_adapter<>` which yields a standard pointer.

A `_Storage_policy` is required to provide 4 things: 1) A `get()` API for returning the stored pointer value. 2) An `set()` API for storing a pointer value. 3) An `element_type` typedef to define the type this points to. 4) An `operator<()` to support pointer comparison. 5) An `operator==()` to support pointer comparison.

template<typename _Tp>

5.32.2 Member Function Documentation

5.32.2.1 `template<typename _Tp> pointer __gnu_cxx::bitmap_allocator<_Tp>::_M_allocate_single_object () throw std::bad_alloc) [inline]`

Allocates memory for a single object of size `sizeof(_Tp)`.

Exceptions

<code>std::bad_alloc.</code>	If memory can not be allocated.
------------------------------	---------------------------------

Complexity: Worst case complexity is $O(N)$, but that is hardly ever hit. If and when this particular case is encountered, the next few cases are guaranteed to have a worst case complexity of $O(1)$! That's why this function performs very well on average. You can consider this function to have a complexity referred to commonly as: Amortized Constant time.

Definition at line 827 of file `bitmap_allocator.h`.

References `__gnu_cxx::__detail::__bit_allocate()`, `__gnu_cxx::__detail::__num_bitmaps()`, and `__gnu_cxx::_Bit_scan←_forward()`.

5.32.2.2 `template<typename _Tp> void __gnu_cxx::bitmap_allocator<_Tp>::_M_deallocate_single_object (pointer __p) throw) [inline]`

Deallocates memory that belongs to a single object of size `sizeof(_Tp)`.

Complexity: $O(\lg(N))$, but the worst case is not hit often! This is because containers usually deallocate memory close to each other and this case is handled in $O(1)$ time by the deallocate function.

5.33.1 Detailed Description

```
template<typename _CharT>
struct __gnu_cxx::char_traits<_CharT>
```

Base class used to implement `std::char_traits`.

Note

For any given actual character type, this definition is probably wrong. (Most of the member functions are likely to be right, but the `int_type` and `state_type` typedefs, and the `eof()` member function, are likely to be wrong.) The reason this class exists is so users can specialize it. Classes in namespace `std` may not be specialized for fundamental types, but classes in namespace `__gnu_cxx` may be.

See https://gcc.gnu.org/onlinedocs/libstdc++/manual/strings.html#strings.string.character_types for advice on how to make use of this class for *unusual* character types. Also, check out `include/ext/pod_char_traits.h`.

5.40.2 Member Function Documentation

5.40.2.1 `void std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::_M_create_pback()` `[inline]`, `[protected]`, `[inherited]`

Initializes pback buffers, and moves normal buffers to safety. Assumptions: `_M_in_cur` has already been moved back

Definition at line 191 of file `fstream`.

5.40.2.2 `void std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::_M_destroy_pback()` `throw` `[inline]`, `[protected]`, `[inherited]`

Deactivates pback buffer contents, and restores normal buffer. Assumptions: The pback buffer has only moved forward.

Definition at line 208 of file `fstream`.

5.40.2.3 `void std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::_M_set_buffer(streamsize __off)` `[inline]`, `[protected]`, `[inherited]`

This function sets the pointers of the internal buffer, both get and put areas. Typically:

`__off == egptr() - eback()` upon underflow/uflow (**read** mode); `__off == 0` upon overflow (**write** mode); `__off == -1` upon open, setbuf, seekoff/pos (**uncommitted** mode).

NB: `egptr() - pbase() == _M_buf_size - 1`, since `_M_buf_size` reflects the actual allocated memory and the last cell is reserved for the overflow char of a full put area.

Definition at line 422 of file `fstream`.

5.40.2.4 `__filebuf_type* std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::close()` `[inherited]`

Closes the currently associated file.

Returns

`this` on success, `NULL` on failure

If no file is currently open, this function immediately fails.

If a *put buffer area* exists, `overflow(eof)` is called to flush all the characters. The file is then closed.

If any operations fail, this function also fails.

5.40.2.5 `template<typename _CharT, typename _Traits> char_type* std::basic_streambuf< _CharT, _Traits >::eback ()`
`const [inline], [protected], [inherited]`

Access to the get area.

`[inline], [inherited]`

If `pubimbue(loc)` has been called, then the most recent `loc` is returned. Otherwise the global locale in effect at the time of construction is returned.

5.40.2.11 `virtual void std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::imbue (const locale & __loc)`
`[protected], [virtual], [inherited]`

Changes translations.

Parameters

<code>__loc</code>	A new locale.
--------------------	---------------

Translations done during I/O which depend on the current locale are changed by this call. The standard adds, *Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.*

Note

Base class version does nothing.

Reimplemented from [std::basic_streambuf<_CharT, _Traits>](#).

Definition at line 284 of file streambuf.

5.40.2.13 `bool std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::is_open () const throw` `[inline], [inherited]`

Opens an external file.

Parameters

<code>__s</code>	The name of the file.
<code>__mode</code>	The open mode flags.

Returns

`this` on success, NULL on failure

If a file is already open, this function immediately fails. Otherwise it tries to open the file named `__s` using the flags given in `__mode`.

Table 92, adapted here, gives the relation between openmode combinations and the equivalent `fopen()` flags. (NB: lines `app`, `in|out|app`, `in|app`, `binary|app`, `binary|in|out|app`, and `binary|in|app` per DR 596)

Definition at line 307 of file `fstream`.

5.40.2.16 `virtual int_type std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::overflow (int_type __c = _Traits::eof()) [protected], [virtual], [inherited]`

Consumes data from the buffer; writes to the controlled sequence.

Parameters

<code>__c</code>	An additional character to consume.
------------------	-------------------------------------

Returns

`eof()` to indicate failure, something else (usually `__c`, or `not_eof()`)

Informally, this function is called when the output buffer is full (or does not exist, as buffering need not actually be done). If a buffer exists, it is *consumed*, with *some effect* on the controlled sequence. (Typically, the buffer is written out to the sequence verbatim.) In either case, the character `c` is also written out, if `__c` is not `eof()`.

For a formal definition of this function, see a good text such as Langer & Kreft, or [27.5.2.4.5]/3-7.

A functioning output streambuf can be created by overriding only this function (no buffer area will be used).

Note

Base class version does nothing, returns `eof()`.

Reimplemented from [std::basic_streambuf<_CharT, _Traits>](#).

5.40.2.17 `virtual int_type std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::pbackfail (int_type __c = _Traits::eof()) [protected], [virtual], [inherited]`

Parameters

<code>__c</code>	The character to be inserted back into the sequence.
------------------	--

Returns

`eof()` on failure, *some other value* on success

Postcondition

The constraints of `gptr()`, `eback()`, and `pptr()` are the same as for `underflow()`.

Note

Base class version does nothing, returns `eof()`.

Reimplemented from [std::basic_streambuf<_CharT, _Traits>](#).

5.40.2.18 `template<typename _CharT, typename _Traits> char_type* std::basic_streambuf<_CharT, _Traits>::pbase ()`

If no file has been opened, and both `__s` and `__n` are zero, then the stream becomes unbuffered. Otherwise, `__s` is used as a buffer; see <https://gcc.gnu.org/onlinedocs/libstdc++/manual/streambufs.html#io.streambuf.buffering> for more.

Definition at line 338 of file `streambuf`.

Referenced by `std::istreambuf_iterator<_CharT, _Traits>::equal()`, `std::ostreambuf_iterator<_CharT, _Traits>::failed()`, `std::basic_istream<_CharT, _Traits>::get()`, `std::basic_istream<_CharT, _Traits>::getline()`, `std::basic_istream<_CharT, _Traits>::ignore()`, `std::basic_istream<_CharT, _Traits>::sentry::sentry()`, and `std::basic_streambuf<_CharT, _Traits>::xsputn()`.

Definition at line 357 of file `streambuf`.

5.40.2.34 `virtual streamsize std::basic_filebuf<_CharT,encoding_char_traits<_CharT>>::showmanyc ()`
`[protected],[virtual],[inherited]`

Investigating the data available.

Returns

An estimate of the number of characters available in the input sequence, or -1.

If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been supplied. If `showmanyc()` returns -1, then calls to `underflow()` or `uflow()` will fail. [27.5.2.4.3]/1

Note

Base class version does nothing, returns zero.

The standard adds that *the intention is not only that the calls [to `underflow` or `uflow`] will not return `eof()` but that they will return immediately.*

The standard adds that *the morphemes of `showmanyc` are **es-how-many-see**, not **show-manic**.*

Parameters

<code>__c</code>	The character to push back.
------------------	-----------------------------

Returns

The previous character, if possible.

Similar to `sungetc()`, but `__c` is pushed onto the stream instead of *the previous character*. If successful, the next character fetched from the input stream will be `__c`.

Definition at line 372 of file `streambuf`.

Referenced by `std::basic_istream<_CharT, _Traits>::putback()`.

5.40.2.37 `template<typename _CharT, typename _Traits> int_type std::basic_streambuf<_CharT, _Traits>::sputc (char_type __c) [inline], [inherited]`

Entry point for all single-character output functions.

Parameters

<code>__c</code>	A character to output.
------------------	------------------------

Returns

`__c`, if possible.

One of two public output functions.

If a write position is available for the output sequence (i.e., the buffer is not full), stores `__c` in that position, increments the position, and returns `traits::to_int_type(__c)`. If a write position is not available, returns `overflow(__c)`.

Entry point for all single-character output functions.

Parameters

<code>__s</code>	A buffer read area.
<code>__n</code>	A count.

One of two public output functions.

Returns `xspn(__s,__n)`. The effect is to write `__s[0]` through `__s[__n-1]` to the output sequence, if possible.

Definition at line 450 of file `streambuf`.

Referenced by `std::ostreambuf_iterator<_CharT, _Traits >::failed()`.

5.40.2.39 `template<typename _CharT, typename _Traits> int_type std::basic_streambuf<_CharT, _Traits >::sungetc ()`
`[inline], [inherited]`

Moving backwards in the input stream.

Returns

The previous character, if possible.

If a putback position is available, this function decrements the input pointer and returns that character. Otherwise, calls and returns `pbackfail()`. The effect is to *unget* the last character *gotten*.

Definition at line 397 of file `streambuf`.

Referenced by `std::basic_istream<_CharT, _Traits >::unget()`.

5.40.2.40 `virtual int std::basic_filebuf<_CharT, encoding_char_traits<_CharT > >::sync (void)` `[protected],`
`[virtual], [inherited]`

Synchronizes the buffer arrays with the controlled sequences.

Returns

-1 on failure.

Each derived class provides its own appropriate behavior, including the definition of *failure*.

Note

Base class version does nothing, returns zero.

Reimplemented from [std::basic_streambuf<_CharT, _Traits >](#).

5.40.2.41 `template<typename _CharT, typename _Traits> virtual int_type std::basic_streambuf<_CharT, _Traits>::uflow ()` `[inline], [protected], [virtual], [inherited]`

Fetches more data from the controlled sequence.

Returns

The first character from the *pending sequence*.

Informally, this function does the same thing as `underflow()`, and in fact is required to call that function. It also returns the new character, like `underflow()` does. However, this function also moves the read position forward by one.

Reimplemented in `__gnu_cxx::stdio_sync_filebuf<_CharT, _Traits>`.

Definition at line 700 of file `streambuf`.

5.40.2.42 `virtual int_type std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::underflow ()` `[protected], [virtual], [inherited]`

Fetches more data from the controlled sequence.

Returns

The first character from the *pending sequence*.

Informally, this function is called when the input buffer is exhausted (or does not exist, as buffering need not actually be done). If a buffer exists, it is *refilled*. In either case, the next available character is returned, or `traits::eof()` to indicate a null pending sequence.

For a formal definition of the pending sequence, see a good text such as Langer & Kreft, or [27.5.2.4.3]/7-14.

A functioning input streambuf can be created by overriding only this function (no buffer area will be used). For an example, see <https://gcc.gnu.org/onlinedocs/libstdc++/manual/streambufs.html>

Note

Base class version does nothing, returns `eof()`.

Reimplemented from `std::basic_streambuf<_CharT, _Traits>`.

5.40.2.43 `virtual streamsize std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::xsgetn (char_type * __s, streamsize __n)` `[protected], [virtual], [inherited]`

Multiple character extraction.

Parameters

<code>__s</code>	A buffer area.
<code>__n</code>	Maximum number of characters to assign.

Returns

The number of characters assigned.

Fills `__s[0]` through `__s[__n-1]` with characters from the input sequence, as if by `sbumpc()`. Stops when either `__n` characters have been copied, or when `traits::eof()` would be copied.

It is expected that derived classes provide a more efficient implementation by overriding this definition.

Reimplemented from [std::basic_streambuf<_CharT, _Traits>](#).

5.40.2.44 `virtual streamsize std::basic_filebuf<_CharT, encoding_char_traits<_CharT>>::xsputn (const char_type * __s, streamsize __n)` [protected], [virtual], [inherited]

Multiple character insertion.

Parameters

<code>__s</code>	A buffer area.
<code>__n</code>	Maximum number of characters to write.

Returns

The number of characters written.

Writes `__s[0]` through `__s[__n-1]` to the output sequence, as if by `sputc()`. Stops when either `n` characters have been copied, or when `sputc()` would return `traits::eof()`.

It is expected that derived classes provide a more efficient implementation by overriding this definition.

Definition at line 521 of file `bitmap_allocator.h`.

5.44.2 Member Function Documentation

5.44.2.1 void `__gnu_cxx::free_list::_M_clear` ()

5.44.2.2 `size_t *` `__gnu_cxx::free_list::_M_get` (`size_t __sz`) throw `std::bad_alloc`

This function gets a block of memory of the specified size from the free list.

Parameters

<code>__sz</code>	The size in bytes of the memory required.
-------------------	---

Returns

A pointer to the new memory block of size at least equal to that requested.

5.44.2.3 `void __gnu_cxx::free_list::M_insert (size_t * __addr) throw () [inline]`

This function returns the block of memory to the internal free list.

Parameters

<code>__addr</code>	The pointer to the memory block that was given by a call to the <code>_M_get</code> function.

5.62.1 Detailed Description

Exception thrown by `__cxa_guard_acquire`.

6.7[stmt.dcl]/4: If control re-enters the declaration (recursively) while the object is being initialized, the behavior is undefined.

Since we already have a library function to handle locking, we might as well check for this situation and throw an exception. We use the second byte of the guard variable to remember that we're in the middle of an initialization.

5.67.1 Detailed Description

```
template<typename _CharT, typename _Traits = std::char_traits<_CharT>>
class __gnu_cxx::stdio_filebuf< _CharT, _Traits >
```

Provides a layer of compatibility for C/POSIX.

This GNU extension provides extensions for working with standard C FILE*'s and POSIX file descriptors. It must be instantiated by the user with the type of character used in the file stream, e.g., `stdio_filebuf<char>`.

Definition at line 50 of file `stdio_filebuf.h`.

5.67.2 Constructor & Destructor Documentation

5.67.2.1 `template<typename _CharT, typename _Traits = std::char_traits<_CharT>> __gnu_cxx::stdio_filebuf< _CharT, _Traits>::stdio_filebuf ()` `[inline]`

deferred initialization

Definition at line 65 of file `stdio_filebuf.h`.

References `__gnu_cxx::stdio_filebuf< _CharT, _Traits>::~~stdio_filebuf()`.

Referenced by `__gnu_cxx::stdio_filebuf< _CharT, _Traits>::stdio_filebuf()`, and `__gnu_cxx::stdio_filebuf< _CharT, _Traits>::~~stdio_filebuf()`.

5.67.2.2 `template<typename _CharT, typename _Traits> __gnu_cxx::stdio_filebuf< _CharT, _Traits>::stdio_filebuf (int __fd, std::ios_base::openmode __mode, size_t __size = static_cast<size_t>(BUFSIZ))`

Parameters

<code>__fd</code>	An open file descriptor.
<code>__mode</code>	Same meaning as in a standard filebuf.
<code>__size</code>	Optimal or preferred size of internal buffer, in chars.

This constructor associates a file stream buffer with an open POSIX file descriptor. The file descriptor will be automatically closed when the `stdio_filebuf` is closed/destroyed.

Definition at line 137 of file `stdio_filebuf.h`.

Parameters

<code>__f</code>	An open <code>FILE*</code> .
<code>__mode</code>	Same meaning as in a standard filebuf.
<code>__size</code>	Optimal or preferred size of internal buffer, in chars. Defaults to system's <code>BUFSIZ</code> .

5.67.3.1 `template<typename _CharT, typename _Traits> void std::basic_filebuf<_CharT, _Traits>::_M_create_pback ()`

5.67.3.3 `template<typename _CharT, typename _Traits> void std::basic_filebuf<_CharT, _Traits>::_M_set_buffer (streamsize __off) [inline], [protected], [inherited]`

This function sets the pointers of the internal buffer, both get and put areas. Typically:

`__off == egptr() - eback()` upon underflow/uflow (**read** mode); `__off == 0` upon overflow (**write** mode); `__off == -1` upon open, setbuf, seekoff/pos (**uncommitted** mode).

NB: `eptr() - pbase() == _M_buf_size - 1`, since `_M_buf_size` reflects the actual allocated memory and the last cell is reserved for the overflow char of a full put area.

5.67.3.4 `template<typename _CharT, typename _Traits> basic_filebuf<_CharT, _Traits>::_filebuf_type * std::basic_filebuf<_CharT, _Traits>::close () [inherited]`

Closes the currently associated file.

Returns

`this` on success, NULL on failure

If no file is currently open, this function immediately fails.

If a *put buffer area* exists, `overflow(eof)` is called to flush all the characters. The file is then closed.

If any operations fail, this function also fails.

5.67.3.18 `template<typename _CharT, typename _Traits> basic_filebuf<_CharT, _Traits>::int_type std::basic_filebuf<_CharT, _Traits>::overflow (int_type __c = _Traits::eof()) [protected], [virtual], [inherited]`

Consumes data from the buffer; writes to the controlled sequence.

Parameters

<code>__c</code>	An additional character to consume.
------------------	-------------------------------------

Returns

`eof()` to indicate failure, something else (usually `__c`, or `not_eof()`)

Informally, this function is called when the output buffer is full (or does not exist, as buffering need not actually be done). If a buffer exists, it is *consumed*, with *some effect* on the controlled sequence. (Typically, the buffer is written out to the sequence verbatim.) In either case, the character `c` is also written out, if `__c` is not `eof()`.

For a formal definition of this function, see a good text such as Langer & Kreft, or [27.5.2.4.5]/3-7.

A functioning output streambuf can be created by overriding only this function (no buffer area will be used).

Note

Base class version does nothing, returns `eof()`.

Tries to back up the input sequence.

Parameters

<code>__c</code>	The character to be inserted back into the sequence.
------------------	--

Returns

`eof()` on failure, *some other value* on success

Postcondition

The constraints of `gptr()`, `eback()`, and `pptr()` are the same as for `underflow()`.

Note

std::basic_filebuf<_CharT, _Traits>::setbuf (char_type * __s, streamsize __n)` [protected],
[virtual], [inherited]

Manipulates the buffer.

Parameters

<code>__s</code>	Pointer to a buffer area.
<code>__n</code>	Size of <code>__s</code> .

Returns

`this`

If no file has been opened, and both `__s` and `__n` are zero, then the stream becomes unbuffered. Otherwise, `__s` is used as a buffer; see <https://gcc.gnu.org/onlinedocs/libstdc++/manual/streambufs.html#io.streambuf.buffering> for more.

Parameters

Setting the three write area pointers.

Parameters

<code>__pbeg</code>	A pointer.
<code>__pend</code>	A pointer.

Postcondition

Definition at line 555 of file streambuf.

5.67.3.34 `template<typename _CharT, typename _Traits> int_type std::basic_streambuf<_CharT, _Traits>::sgetc () [inline], [inherited]`

Getting the next character.

Returns

The next character, or eof.

If the input read position is available, returns that character, otherwise calls and returns `underflow()`. Does not move the read position after fetching the character.

Entry point for `xsgetn`.

Parameters

<code>__s</code>	A buffer area.
<code>__n</code>	A count.

Returns `xsgntrn(__s, __n)`. The effect is to fill `__s[0]` through `__s[__n-1]` with characters from the input sequence, if possible.

Definition at line 357 of file `streambuf`.

5.67.3.36 `template<typename _CharT, typename _Traits> streamsize std::basic_filebuf<_CharT, _Traits>::showmanyc ()`
`[protected], [virtual], [inherited]`

Investigating the data available.

Returns

An estimate of the number of characters available in the input sequence, or -1.

If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been supplied. If `showmanyc()` returns -1, then calls to `underflow()` or `uflow()` will fail. [27.5.2.4.3]/1

Note

Base class version does nothing, returns zero.

The standard adds that *the intention is not only that the calls [to `underflow` or `uflow`] will not return `eof()` but that they will return immediately.*

The standard adds that *the morphemes of `showmanyc` are **es-how-many-see**, not **show-manic**.*

`char_type __c) [inline], [inherited]`

Parameters

<code>__c</code>	The character to push back.
------------------	-----------------------------

Returns

The previous character, if possible.

Similar to `sungetc()`, but `__c` is pushed onto the stream instead of *the previous character*. If successful, the next character fetched from the input stream will be `__c`.

Parameters

<code>__c</code>	A character to output.
------------------	------------------------

Returns

`__c`, if possible.

One of two public output functions.

If a write position is available for the output sequence (i.e., the buffer is not full), stores `__c` in that position, increments the position, and returns `traits::to_int_type(__c)`. If a write position is not available, returns `overflow(__c)`.

Parameters

<code>__s</code>	A buffer read area.
<code>__n</code>	A count.

Returns

The previous character, if possible.

`[inline], [protected], [virtual], [inherited]`

Fetches more data from the controlled sequence.

Returns

The first character from the *pending sequence*.

Informally, this function does the same thing as `underflow()`, and in fact is required to call that function. It also returns the new character, like `underflow()` does. However, this function also moves the read position forward by one.

`[protected], [virtual], [inherited]`

Fetches more data from the controlled sequence.

Returns

The first character from the *pending sequence*.

Informally, this function is called when the input buffer is exhausted (or does not exist, as buffering need not actually be done). If a buffer exists, it is *refilled*. In either case, the next available character is returned, or `traits::eof()` to indicate a null pending sequence.

For a formal definition of the pending sequence, see a good text such as Langer & Kreft, or [27.5.2.4.3]/7-14.

A functioning input streambuf can be created by overriding only this function (no buffer area will be used). For an example, see <https://gcc.gnu.org/onlinedocs/libstdc++/manual/streambufs.html>

Multiple character extraction.

Parameters

<code>__s</code>	A buffer area.
<code>__n</code>	Maximum number of characters to assign.

Returns

The number of characters assigned.

Fills `__s[0]` through `__s[__n-1]` with characters from the input sequence, as if by `sbumpc()`. Stops when either `__n` characters have been copied, or when `traits::eof()` would be copied.

5.68.1 Detailed Description

```
template<typename _CharT, typename _Traits = std::char_traits<_CharT>>
class __gnu_cxx::stdio_sync_filebuf< _CharT, _Traits >
```

Provides a layer of compatibility for C.

This GNU extension provides extensions for working with standard C FILE*'s. It must be instantiated by the user with the type of character used in the file stream, e.g., `stdio_filebuf<char>`.

5.68.2 Member Function Documentation

5.68.2.1 `template<typename _CharT, typename _Traits> char_type* std::basic_streambuf< _CharT, _Traits >::eback ()`
`const [inline], [protected], [inherited]`

Access to the get area.

These functions are only available to other protected functions, including derived classes.

- `eback()` returns the beginning pointer for the input sequence
- `gptr()` returns the next pointer for the input sequence
- `egptr()` returns the end pointer for the input sequence

Definition at line 482 of file `streambuf`.

Referenced by `std::basic_filebuf< _CharT, _Traits >::imbue()`, `std::basic_filebuf< _CharT, _Traits >::pbackfail()`, `std::basic_filebuf< _CharT, _Traits >::seekpos()`, `std::basic_filebuf< _CharT, _Traits >::underflow()`, and `std::basic_filebuf< _CharT, _Traits >::xsgetn()`.

5.68.2.2 `template<typename _CharT, typename _Traits> char_type* std::basic_streambuf<_CharT, _Traits>::egptr ()`
`const [inline], [protected], [inherited]`

Access to the get area.

These functions are only available to other protected functions, including derived classes.

- `eback()` returns the beginning pointer for the input sequence
- `gptr()` returns the next pointer for the input sequence
- `egptr()` returns the end pointer for the input sequence

5.68.2.3 `template<typename _CharT, typename _Traits> char_type* std::basic_streambuf<_CharT, _Traits>::epptr ()`
`const [inline], [protected], [inherited]`

Access to the put area.

These functions are only available to other protected functions, including derived classes.

- `pbase()` returns the beginning pointer for the output sequence
- `pptr()` returns the next pointer for the output sequence
- `epptr()` returns the end pointer for the output sequence

Definition at line 535 of file `streambuf`.

5.68.2.4 `template<typename _CharT, typename _Traits = std::char_traits<_CharT>> std::__c_file*`
`__gnu_cxx::stdio_sync_filebuf<_CharT, _Traits>::file () [inline]`

Returns

The underlying `FILE*`.

This function can be used to access the underlying C file pointer. Note that there is no way for the library to track what you do with the file, so be careful.

Definition at line 118 of file `stdio_sync_filebuf.h`.

5.68.2.5 `template<typename _CharT, typename _Traits> void std::basic_streambuf<_CharT, _Traits>::gbump (int __n)`
`[inline], [protected], [inherited]`

Moving the read position.

Parameters

<code>_↔</code>	The delta by which to move.
<code>_n</code>	

This just advances the read position without returning any data.
